## Theory

# Linear Discriminant Analysis

R. Gutierrez-Osuna, [http://research.cs.tamu.edu/prism/lectures/pr/pr\\_l10.pdf](http://research.cs.tamu.edu/prism/lectures/pr/pr_l10.pdf)

## Input

$$\mathcal{E} = \{(\mathbf{x}_i, y_i), \mathbf{x}_i \in \mathbb{R}^d, y_i \in \{+1, -1\}, i = 1 \dots n\}$$

## Output

$$h(\mathbf{x}) = \langle \mathbf{w}, \mathbf{x} \rangle \quad \hat{y} = \text{sg}(h(\mathbf{x}))$$

## Remark

One might need  $\langle \mathbf{w}, \mathbf{x} \rangle + b$

Solution:  $\mathbf{x} = (x_1, \dots, x_d) \in \mathbb{R}^d \mapsto \mathbf{x}' = (x_1, \dots, x_d, 1) \in \mathbb{R}^{d+1}$   
and  $\mathbf{w} \in \mathbb{R}^d \mapsto \mathbf{w}' = (w_1, \dots, w_d, b) \in \mathbb{R}^{d+1}$

$$\langle \mathbf{w}, \mathbf{x} \rangle + b = \langle \mathbf{w}', \mathbf{x}' \rangle$$

# LDA, 2

## Criterion

Find  $\mathbf{w}$  s.t. it maximizes the discrimination.

## Define

$\mu_+ = \text{average of } \mathbf{x}_i \text{ s.t. } y_i = +1$

$\mu_- = \text{average of } \mathbf{x}_i \text{ s.t. } y_i = -1$

## Build

$\mathbf{w}$  s.t.  $\langle \mathbf{w}, \mu_+ - \mu_- \rangle = 0$

## LDA, 3

# LDA, 4

## Intuition

Characterize the variance:

within-class scatter matrix

$$S_W = \sum_{\mathbf{x}_i, y_i=1} (\mathbf{x}_i - \mu_+).(\mathbf{x}_i - \mu_+)' + \sum_{\mathbf{x}_i, y_i=-1} (\mathbf{x}_i - \mu_-).(\mathbf{x}_i - \mu_-)'$$

Characterize the difference:

between-class scatter matrix

$$S_B = (\mu_+ - \mu_-).(\mu_+ - \mu_-)'$$

## Solution

$$\text{find } \mathbf{w} = \underset{\mathbf{w}}{\operatorname{argmax}} \frac{\mathbf{w}' S_B \mathbf{w}}{\mathbf{w}' S_W \mathbf{w}}$$

# Some limitations

**There is another limitation:** any idea ?

# Overview

Linear Discriminant Analysis

Linear SVM, separable case

Linear SVM, non separable case

The kernel trick

- The Kernel principle

- Examples

- Discussion

Extensions

- Multi-class discrimination

- Regression

- Novelty detection

On the practitioner side

- Improve precision

- Reduce computational cost

Theory

# The separable case: More than one separating hyperplane

# Linear Support Vector Machines

## Linear Separators

$$f(\mathbf{x}) = \langle \mathbf{w}, \mathbf{x} \rangle + b$$

Region  $\hat{y} = 1$ :  $f(\mathbf{x}) > 0$

Region  $\hat{y} = -1$ :  $f(\mathbf{x}) < 0$

## Criterion

$$\forall i, y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) > 0$$

## Remark

Invariant by multiplication of  $\mathbf{w}$  and  $b$  by a positive value

# Canonical formulation

Fix the scale:

$$\min_i \{y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b)\} = 1$$

$\Leftrightarrow$

$$\forall i, y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1$$

# Maximize the Margin

## Criterion

Maximize the minimal distance (points, hyperplane).

*Obtain the largest possible band*

## Margin

$$\langle \mathbf{w}, \mathbf{x}_+ \rangle + b = 1 \quad \langle \mathbf{w}, \mathbf{x}_- \rangle + b = -1$$

$$\langle \mathbf{w}, \mathbf{x}_+ - \mathbf{x}_- \rangle = 2$$

Margin = projection of  $\mathbf{x}_+ - \mathbf{x}_-$  on the normal vector of the hyperplane,  $\frac{\mathbf{w}}{\|\mathbf{w}\|_2}$

$$\Rightarrow \text{Maximize } \frac{1}{\|\mathbf{w}\|}$$

$$\Leftrightarrow \text{minimize } \|\mathbf{w}\|^2$$

# Maximal Margin Hyperplane

# Maximize the Margin (2)

## Problem

$$\begin{cases} \text{Minimize} & \frac{1}{2} \|\mathbf{w}\|^2 \\ \text{with the constraints} & \forall i, y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1 \end{cases}$$

# Primal Problem

$$\text{Min}_{\mathbf{w}, b} \text{Max}_{\alpha \geq 0} L(\mathbf{w}, b, \alpha) = \frac{1}{2} \|\mathbf{w}\|^2 - \sum_i \alpha_i (y_i (\langle \mathbf{x}_i, \mathbf{w} \rangle + b) - 1), \quad \alpha_i \geq 0$$

- Differentiate w.r.t.  $b$ : at the optimum,

$$\frac{\partial L}{\partial b} = 0 = \sum \alpha_i y_i$$

- Differentiate w.r.t.  $\mathbf{w}$ :

$$\frac{\partial L}{\partial \mathbf{w}} = 0 = \mathbf{w} - \sum \alpha_i y_i \mathbf{x}_i$$

- Replace in  $L(\mathbf{w}, b, \alpha)$ :

# Dual problem (Wolfe)

$$\left\{ \begin{array}{l} \text{Maximize} \\ \text{with the constraint} \end{array} \right. \quad \begin{array}{l} W(\alpha) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle \\ \forall i, \alpha_i \geq 0 \\ \sum_i \alpha_i y_i = 0 \end{array}$$

**Quadratic form w.r.t.  $\alpha$**

quadratic optimization is easy

Solution:  $\alpha_i^*$

- Compute  $\mathbf{w}^*$  :

$$\mathbf{w}^* = \sum_i \alpha_i^* y_i \mathbf{x}_i$$

- If  $(\langle \mathbf{x}_i, \mathbf{w}^* \rangle + b) y_i > 1$ ,  $\alpha_i^* = 0$ .
- If  $\alpha_i^* > 0$ , then  $(\langle \mathbf{x}_i, \mathbf{w}^* \rangle + b) y_i = 1$   $\mathbf{x}_i$     **support vector**
- Compute  $b^*$  :

$$b^* = -\frac{1}{2}(\langle \mathbf{w}^*, \bar{\mathbf{x}}^+ \rangle + \langle \mathbf{w}^*, \bar{\mathbf{x}}^- \rangle)$$

# Summary

$$\mathcal{E} = \{(\mathbf{x}_i, y_i)\}, \mathbf{x}_i \in \mathbb{R}^d, y_i \in \{-1, 1\}, i = 1..n \quad (\mathbf{x}_i, y_i) \sim P(\mathbf{x}, y)$$

$$h(\mathbf{x}) = \langle \mathbf{w}, \mathbf{x} \rangle + b$$

## Two goals

## Role

- ▶ Data fitting  
 $\text{sign}(y_i) = \text{sign}(h(\mathbf{x}_i)) \rightarrow \text{maximize margin } y_i \cdot h(\mathbf{x}_i)$

achieve learning

- ▶ Regularization : minimize  $\|\mathbf{w}\|$

avoid overfitting

# Support Vector Machines

## General scheme

- ▶ Minimize the regularization term
- ▶ ... subject to data constraints  $\quad \quad \quad = \text{margin} \geq 1 \text{ (*)}$

$$\begin{cases} \text{Min.} & \frac{1}{2} \|\mathbf{w}\|^2 \\ \text{s.t.} & y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1 \quad \forall i = 1 \dots n \end{cases}$$

## Constrained minimization of a convex function

→ introduce Lagrange multipliers  $\alpha_i \geq 0, i = 1 \dots n$

$$\text{Min } \mathcal{L}(\mathbf{w}, b, \alpha) = \frac{1}{2} \|\mathbf{w}\|^2 + \sum_i \alpha_i (1 - y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b))$$

## Primal problem

- ▶  $d + 1$  variables (+  $n$  Lagrange multipliers)

(\*) in the separable case; see later for non-separable case

# Support Vector Machines, 2

At the optimum

$$\frac{\partial \mathcal{L}}{\partial \mathbf{w}} = \frac{\partial \mathcal{L}}{\partial b} = \frac{\partial \mathcal{L}}{\partial \alpha} = 0$$

Dual problem

Wolfe

$$\left\{ \begin{array}{ll} \text{Max.} & \mathcal{Q}(\alpha) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle \\ \text{s.t.} & \forall i, \alpha_i \geq 0 \\ & \sum_i \alpha_i y_i = 0 \end{array} \right.$$

Support vectors

Examples  $(\mathbf{x}_i, y_i)$  s.t.  $\alpha_i > 0$

the only ones involved in the decision function

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i$$

# Support vectors, examples

# Support vectors, examples

## MNIST data

Data

Support vectors

## Remarks

- ▶ Support vectors are critical examples near-miss
- ▶ Show that the Leave-One-Out error is less than  $\#$  sv.

LOO: iteratively, learn on all examples but one, and test on the remaining one

# Overview

Linear Discriminant Analysis

Linear SVM, separable case

Linear SVM, non separable case

The kernel trick

- The Kernel principle

- Examples

- Discussion

Extensions

- Multi-class discrimination

- Regression

- Novelty detection

On the practitioner side

- Improve precision

- Reduce computational cost

Theory

# Separable vs non-separable data

Training

Test

# Linear hypotheses, non separable data

Cortes & Vapnik 95

Non-separable data  $\Rightarrow$  not all constraints are satisfiable

$$y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1 - \xi_i$$

## Formalization

- ▶ Introduce slack variables  $\xi_i$
- ▶ And penalize them

$$\begin{cases} \text{Minimize} & \frac{1}{2} \|\mathbf{w}\|^2 + \mathbf{C} \sum_i \xi_i \\ \text{Subject to} & \forall i, y_i(\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq 1 - \xi_i \\ & \xi_i \geq 0 \end{cases}$$

**Critical decision:** adjust  $C =$  error cost.

# Primal problem, non separable case

**Same resolution:** Lagrange Multipliers  $\alpha_i$  and  $\beta_i$ , with  $\alpha_i \geq 0$ ,  $\beta_i \geq 0$

$$\begin{aligned}\mathcal{L}(\mathbf{w}, b, \xi, \alpha, \beta) = & \text{Min}_{\mathbf{w}, b, \xi} \text{Max}_{\alpha, \beta} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_i \xi_i \\ & - \sum_i \alpha_i (y_i (\langle \mathbf{w}, \mathbf{x}_i \rangle + b) - 1 + \xi_i) \\ & - \sum_i \beta_i \xi_i\end{aligned}$$

**At the optimum**

$$\frac{\partial \mathcal{L}}{\partial \mathbf{w}} = \frac{\partial \mathcal{L}}{\partial b} = \frac{\partial \mathcal{L}}{\partial \xi_i} = 0$$

$$\mathbf{w} = \sum_i \alpha_i y_i \mathbf{x}_i \quad \sum_i \alpha_i y_i = 0 \quad C - \alpha_i - \beta_i = 0$$

**Likewise**

- Convex (quadratic) optimization problem  $\rightarrow$  it is equivalent to solve the primal and the dual problem (expressed with multipliers  $\alpha, \beta$ )

## Dual problem, non separable case

$$\text{Min} \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle, \quad 0 \leq \alpha_i \leq C$$

### Mathematically nice problem

- ▶  $H$  = semi-definite positive  $n \times n$  matrix

$$H_{i,j} = y_i y_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle$$

- ▶ Dual problem

quadratic form

$$\text{Minimize } \langle \alpha, e \rangle - \alpha^T H \alpha$$

with  $e = (1, \dots, 1) \in \mathbb{R}^n$ .

# Support vectors

- ▶ Only support vectors ( $\alpha_i > 0$ ) are involved in  $h$

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i$$

- ▶ Importance of support vector  $\mathbf{x}_i$ : weight  $\alpha_i$
- ▶ Difference with the separable case  $0 < \alpha_i < C$   
bounded influence of examples

# The loss (error cost) function

## Roles

- ▶ The goal is data fitting  
loss function characterizes the learning goal
- ▶ while solving a convex optimization problem  
and makes it tractable/reproducible

## The error cost

- ▶ Binary cost:  $\ell(y, h(\mathbf{x})) = 1$  iff  $y \neq h(\mathbf{x})$
- ▶ Quadratic cost:  $\ell(y, h(\mathbf{x})) = (y - h(\mathbf{x}))^2$
- ▶ Hinge loss

$$\ell(y, h(\mathbf{x})) = \max(0, 1 - y \cdot h(\mathbf{x})) = (1 - y \cdot h(\mathbf{x}))_+ = \xi$$

# Complexity

## Learning complexity

- ▶ Worst case:  $\mathcal{O}(n^3)$
- ▶ Empirical complexity: depends on  $C$
- ▶  $\mathcal{O}(n^2 n_{sv})$  where  $n_{sv}$  is the number of s.v.

## Usage complexity

- ▶  $\mathcal{O}(n_{sv})$

# Overview

Linear Discriminant Analysis

Linear SVM, separable case

Linear SVM, non separable case

## The kernel trick

- The Kernel principle

- Examples

- Discussion

## Extensions

- Multi-class discrimination

- Regression

- Novelty detection

## On the practitioner side

- Improve precision

- Reduce computational cost

## Theory

# Non-separable data

## Representation change

$$\mathbf{x} \in \mathbb{R}^2 \rightarrow \text{polar coordinates} \in \mathbb{R}^2$$

# Principle

$$\Phi : X \mapsto \Phi(X) \subset \mathbb{R}^D$$

## Intuition

- ▶ In a high-dimensional space, every dataset is linearly separable  
→ Map data onto  $\Phi(X)$ , and we are back to linear separation

## Glossary

- ▶  $X$ : input space
- ▶  $\Phi(X)$ : feature space

# The kernel trick

## Remark

- ▶ Generalization bounds do not depend on the dimension of input space  $X$  but on the capacity of the hypothesis space  $\mathcal{H}$ .
- ▶ SVMs only involve scalar products  $\langle \mathbf{x}_i, \mathbf{x}_j \rangle$ .

## Intuition

- ▶ Representation change is only “virtual”  $\Phi : X \mapsto \Phi(X)$
- ▶ Consider scalar product in  $\Phi(X)$
- ▶ ... and compute it in  $X$

$$K(\mathbf{x}_i, \mathbf{x}_j) = \langle \Phi(\mathbf{x}_i), \Phi(\mathbf{x}_j) \rangle$$

# Example: polynomial kernel

## Principle

$$\mathbf{x} \in \mathbb{R}^3 \mapsto \Phi(\mathbf{x}) \in \mathbb{R}^{10}$$

$$\mathbf{x} = (x_1, x_2, x_3)$$

$$\Phi(\mathbf{x}) = (1, \sqrt{2}x_1, \sqrt{2}x_2, \sqrt{2}x_3, \sqrt{2}x_1x_2, \sqrt{2}x_1x_3, \sqrt{2}x_2x_3, x_1^2, x_2^2, x_3^2)$$

Why  $\sqrt{2}$  ?

# Example: polynomial kernel

## Principle

$$\mathbf{x} \in \mathbb{R}^3 \mapsto \Phi(\mathbf{x}) \in \mathbb{R}^{10}$$

$$\mathbf{x} = (x_1, x_2, x_3)$$

$$\Phi(\mathbf{x}) = (1, \sqrt{2}x_1, \sqrt{2}x_2, \sqrt{2}x_3, \sqrt{2}x_1x_2, \sqrt{2}x_1x_3, \sqrt{2}x_2x_3, x_1^2, x_2^2, x_3^2)$$

Why  $\sqrt{2}$  ?

because

$$\langle \Phi(\mathbf{x}), \Phi(\mathbf{x}') \rangle = (1 + \langle \mathbf{x}, \mathbf{x}' \rangle)^2 = K(\mathbf{x}, \mathbf{x}')$$

# Primal and dual problems unchanged

## Primal problem

$$\begin{cases} \text{Min.} & \frac{1}{2} \|\mathbf{w}\|^2 \\ \text{s.t.} & y_i(\langle \mathbf{w}, \Phi(\mathbf{x}_i) \rangle + b) \geq 1 \quad \forall i = 1 \dots n \end{cases}$$

## Dual problem

$$\begin{cases} \text{Max.} & \mathcal{Q}(\alpha) = \sum_i \alpha_i - \frac{1}{2} \sum_{i,j} \alpha_i \alpha_j y_i y_j K(\mathbf{x}_i, \mathbf{x}_j) \\ \text{s.t.} & \forall i, \alpha_i \geq 0 \\ & \sum_i \alpha_i y_i = 0 \end{cases}$$

## Hypothesis

$$h(\mathbf{x}) = \sum_i \alpha_i y_i K(\mathbf{x}_i, \mathbf{x})$$

## Example, polynomial kernel

$$K(\mathbf{x}, \mathbf{x}') = (a\langle \mathbf{x}, \mathbf{x}' \rangle + 1)^b$$

- ▶ Choice of  $a, b$  : cross validation
- ▶ Domination of high/low degree terms ?
- ▶ Importance of normalization

## Example, Radius-Based Function kernel (RBF)

$$K(\mathbf{x}, \mathbf{x}') = \exp(-\gamma \|\mathbf{x} - \mathbf{x}'\|^2)$$

- ▶ No closed form  $\Phi$
- ▶  $\Phi(X)$  of infinite dimension

For  $x$  in  $\mathbb{R}$

$$\Phi(x) = \exp(-\gamma x^2) \left[ 1, \sqrt{\frac{2\gamma}{1!}}x, \sqrt{\frac{(2\gamma)^2}{2!}}x^2, \sqrt{\frac{(2\gamma)^3}{3!}}x^3, \dots \right]$$

- ▶ Choice of  $\gamma$  ? (intuition: think of  $H$ ,  $H_{i,j} = y_i y_j K(\mathbf{x}_i, \mathbf{x}_j)$ )

# String kernels

Watkins 99, Lodhi 02    **Notations**

- ▶  $s$  a string on alphabet  $\Sigma$
- ▶  $\mathbf{i} = (i_1, i_2, \dots, i_n)$  an ordered index sequence ( $i_j < i_{j+1}$ ), avec  $\ell(\mathbf{i}) = i_n - i_1 + 1$
- ▶  $s[\mathbf{i}]$  substring of  $s$ , extraction pattern is  $\mathbf{i}$   
 $s = BICYCLE, \mathbf{i} = (1, 3, 6), s[\mathbf{i}] = BCL$

## Definition

$$K_n(s, s') = \sum_{u \in \Sigma^n} \sum_{\mathbf{i} \text{ s.t. } s[\mathbf{i}] = u} \sum_{\mathbf{j} \text{ s.t. } s'[\mathbf{j}] = u} \varepsilon^{\ell(\mathbf{i}) + \ell(\mathbf{j})}$$

with  $0 < \varepsilon < 1$  (discount)

## String kernels, followed

$\Phi$ : projection on  $\mathbb{R}^D$  où  $D = |\Sigma|^n$

	CH	CA	CT	AT
CHAT	$\varepsilon^2$	$\varepsilon^3$	$\varepsilon^4$	$\varepsilon^2$
CARTOON	0	$\varepsilon^2$	$\varepsilon^4$	$\varepsilon^3$

$$K(\text{CHAT}, \text{CARTON}) = 2\varepsilon^5 + \varepsilon^8$$

Prefer the normalized version

$$\kappa(s, s') = \frac{K(s, s')}{\sqrt{K(s, s)K(s', s')}}}$$

# String kernels, followed

## Application 1

Document mining

- ▶ Pre-processing matters a lot (stop-words, stemming)
- ▶ Multi-lingual aspects
- ▶ Document classification
- ▶ Information retrieval

## Application 2, Bio-informatics

- ▶ Pre-processing matters a lot
- ▶ Classification (secondary structures)

Extension to graph kernels [http://videlectures.net/gbr07\\_vert\\_ckac/](http://videlectures.net/gbr07_vert_ckac/)

# Application to musical analysis

- ▶ Input: Midi files
- ▶ Pre-processing, rythm detection
- ▶ Representation: the musical worm (tempo, loudness)
- ▶ Output: Identification of performer styles

(a)

(b)

Using String Kernels to Identify Famous Performers from their Playing Style, Saunders et al., 2004

# Kernels: key features

## Absolute $\rightarrow$ Relative representation

- ▶  $\langle \mathbf{x}, \mathbf{x}' \rangle \propto$  angle of  $\mathbf{x}$  and  $\mathbf{x}'$
- ▶ More generally  $K(\mathbf{x}, \mathbf{x}')$  measures the (non-linear) similarity of  $\mathbf{x}$  and  $\mathbf{x}'$
- ▶  $\mathbf{x}$  is described by its similarity to other examples

## Necessary condition: the Mercer condition

$K$  must be positive semi-definite

$$\forall g \in L_2, \int K(\mathbf{x}, \mathbf{x}') g(\mathbf{x}) g(\mathbf{x}') d\mathbf{x} \geq 0$$

# Why ?

**Related to  $\Phi$**  Mercer condition holds  $\rightarrow \exists \phi_1, \phi_2, ..$

$$k(\mathbf{x}, \mathbf{x}') = \sum_{i=1}^{\infty} \lambda_i \phi_i(\mathbf{x}) \phi_i(\mathbf{x}')$$

with  $\phi_i$  eigen functions,  $\lambda_i > 0$  eigen values

**Kernel properties:** let  $K, K'$  be p.d. kernels and  $\alpha > 0$ , then

- ▶  $\alpha K$  is a p.d. kernel
- ▶  $K + K'$  is a p.d. kernel
- ▶  $K.K'$  is a p.d. kernel
- ▶  $K(\mathbf{x}, \mathbf{x}') = \lim_{p \rightarrow \infty} K_p(\mathbf{x}, \mathbf{x}')$  is p.d. if it exists
- ▶  $K(A, B) = \sum_{\mathbf{x} \in A, \mathbf{x}' \in B} K(\mathbf{x}, \mathbf{x}')$  is a p.d. kernel

# Overview

Linear SVM, separable case

Linear SVM, non separable case

The kernel trick

- The Kernel principle

- Examples

- Discussion

## Extensions

- Multi-class discrimination

- Regression

- Novelty detection

On the practitioner side

- Improve precision

- Reduce computational cost

Theory

# Multi-class discrimination

## Input

Binary case

$$\mathcal{E} = \{(\mathbf{x}_i, y_i)\}, \mathbf{x}_i \in \mathbb{R}^d, y_i \in \{-1, 1\}, i = 1..n \quad (\mathbf{x}_i, y_i) \sim P(\mathbf{x}, y)$$

Multi-class case

$$\mathcal{E} = \{(\mathbf{x}_i, y_i)\}, \mathbf{x}_i \in \mathbb{R}^d, y_i \in \{1 \dots k\}, i = 1..n \quad (\mathbf{x}_i, y_i) \sim P(\mathbf{x}, y)$$

**Output** :  $\hat{h} : \mathbb{R}^d \mapsto \{1 \dots k\}$ .

# Multi-class learning: one against all

## First option: $k$ binary learning problems

Pb 1: class 1  $\rightarrow +1$ , classes  $2 \dots k \rightarrow -1$

$h_1$

Pb 2: class 2  $\rightarrow +1$ , classes  $1, 3, \dots k \rightarrow -1$

$h_2$

...

## Prediction

$$h(\mathbf{x}) = i \text{ iff } h_i(\mathbf{x}) = \operatorname{argmax}\{h_j(\mathbf{x}), j = 1 \dots k\}$$

## Justification

If  $\mathbf{x}$  belongs to class 1, one should have

$$h_1(\mathbf{x}) \geq 1, h_j(\mathbf{x}) < -1, j \neq 1$$

# Where is the difficulty ?

What we get (one vs all)

What we want

# Multi-class learning: one vs one

**Second option:**  $\frac{k(k-1)}{2}$  binary classification problems

Pb  $i, j$  class  $i \rightarrow +1$ , class  $j \rightarrow -1$

$h_{i,j}$

## Prediction

- ▶ Compute all  $h_{i,j}(\mathbf{x})$
- ▶ Count the votes

Classes		winner					
1	2	1					
1	3	1					
1	4	1					
2	3	2					
2	4	4					
3	4	3					
			class	1	2	3	4
			# votes	3	1	1	1

**NB:** One can also use the  $h_{i,j}(\mathbf{x})$  values.

# Multi-class learning: additional constraints

## Another option

Vapnik 98; Weston, Watkins 99

$$\left\{ \begin{array}{l} \text{Minimise} \quad \frac{1}{2} \sum_{j=1}^k \|\mathbf{w}_j\|^2 + C \sum_{i=1}^n \sum_{\ell=1, \ell \neq y_i}^k \xi_{i,\ell} \\ \text{Subject to} \quad \forall i, \forall \ell \neq y_i, \\ \quad (\langle \mathbf{w}_{y_i}, \mathbf{x}_i \rangle + b_{y_i}) \geq (\langle \mathbf{w}_\ell, \mathbf{x}_i \rangle + b_\ell) + 2 - \xi_{i,\ell} \\ \quad \xi_{i,\ell} \geq 0 \end{array} \right.$$

## Hum !

- ▶  $n \times k$  constraints:  $n \times k$  dual variables

# Recommendations

## In practice

- ▶ Results are in general (but not always !) similar
- ▶ 1-vs-1 is the fastest option

- ▶ ... while being as flat as possible

loss function

regularization

## Formulation

$$\left\{ \begin{array}{ll} \text{Min.} & \frac{1}{2} \|\mathbf{w}\|^2 \\ \text{s.t.} & \forall i = 1 \dots n \\ & (\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq y_i - \varepsilon \\ & (\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \leq y_i + \varepsilon \end{array} \right.$$

# Regression with Support Vector Machines, followed

## Using slack variables

$$\left\{ \begin{array}{ll} \text{Min.} & \frac{1}{2} \|\mathbf{w}\|^2 + \mathbf{C} \sum_i (\xi_i^+ + \xi_i^-) \\ \text{s.t.} & \forall i = 1 \dots n \\ & (\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \geq y_i - \varepsilon - \xi_i^- \\ & (\langle \mathbf{w}, \mathbf{x}_i \rangle + b) \leq y_i + \varepsilon + \xi_i^+ \end{array} \right.$$

# Regression with Support Vector Machines, followed

## Primal problem

$$\begin{aligned}\mathcal{L}(\mathbf{w}, b, \xi, \alpha, \beta) = & \text{Min } \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_i (\xi_i^+ + \xi_i^-) \\ & - \sum_i \alpha_i^+ (y_i + \varepsilon + \xi_i^+ - \langle \mathbf{w}, \mathbf{x}_i \rangle + b) \\ & - \sum_i \alpha_i^- (\langle \mathbf{w}, \mathbf{x}_i \rangle + b - y_i + \varepsilon + \xi_i^-) \\ & - \sum_i \beta_i^+ \xi_i^+ - \sum_i \beta_i^- \xi_i^-\end{aligned}$$

## Dual problem

$$\left\{ \begin{array}{l} \mathcal{Q}(\alpha^+, \alpha^-) = \sum_i y_i (\alpha_i^+ - \alpha_i^-) - \varepsilon \sum_i (\alpha_i^+ + \alpha_i^-) \\ \quad + \sum_{i,j} (\alpha_i^+ - \alpha_i^-) (\alpha_j^+ - \alpha_j^-) \langle \mathbf{x}_i, \mathbf{x}_j \rangle \\ \text{s.t.} \quad \forall i = 1 \dots n \\ \quad \sum (\alpha_i^+ - \alpha_i^-) = 0 \\ \quad 0 \leq \alpha_i^+ \leq C \\ \quad 0 \leq \alpha_i^- \leq C \end{array} \right.$$

# Regression with Support Vector Machines, followed Hypothesis

$$h(\mathbf{x}) = \sum (\alpha_i^+ - \alpha_i^-) \langle \mathbf{x}_i, \mathbf{x} \rangle + b$$

With no loss of generality you can replace everywhere

$$\langle \mathbf{x}, \mathbf{x}' \rangle \rightarrow K(\mathbf{x}, \mathbf{x}')$$

# Beware

## High-dimensional regression

$$\mathcal{E} = \{(\mathbf{x}_i, y_i)\}, \mathbf{x}_i \in \mathbb{R}^D, y_i \in \mathbb{R}, i = 1..n \quad (\mathbf{x}_i, y_i) \sim P(\mathbf{x}, y)$$

A very slippery game if  $D \gg n$  curse of dimensionality

## Dimensionality reduction mandatory

- ▶ Map  $\mathbf{x}$  onto  $\mathbb{R}^d$
- ▶ Central subspace:

$$\pi : X \mapsto S \subset \mathbb{R}^d$$

with  $S$  minimal such that  $y$  and  $\mathbf{x}$  are independent conditionally to  $\pi(\mathbf{x})$ .

Find  $h, \mathbf{w} : y = h(\mathbf{w}, \mathbf{x})$

Theory

# Novelty Detection

## Input

$$\mathcal{E} = \{(x_i)\}, x_i \in X, i = 1..n \quad (x_i) \sim P(x)$$

## Context

- Information retrieval

- Identification of the data support

estimation of distribution

## Critical issue

- Classification approaches not efficient: too much noise

# One-class SVM

## Formulation

$$\begin{cases} \text{Min.} & \frac{1}{2} \|\mathbf{w}\|^2 - \rho + \mathbf{C} \sum_i \xi_i \\ \text{s.t.} & \forall i = 1 \dots n \\ & \langle \mathbf{w}, \mathbf{x}_i \rangle \geq \rho - \xi_i \end{cases}$$

## Dual problem

$$\begin{cases} \text{Min.} & \sum_{i,j} \alpha_i \alpha_j \langle \mathbf{x}_i, \mathbf{x}_j \rangle \\ \text{s.t.} & \forall i = 1 \dots n \quad 0 \leq \alpha_i \leq C \\ & \sum_i \alpha_i = 0 \end{cases}$$

# Implicit surface modelling

Schoelkopf et al, 04   **Goal:** find the surface formed by the data points

$$\langle \mathbf{w}, \mathbf{x}_i \rangle \geq \rho \text{ becomes } -\varepsilon \leq (\langle \mathbf{w}, \mathbf{x}_i \rangle - \rho) \leq \varepsilon$$

Theory

# Normalisation / Scaling

Needed to prevent attributes to steal the game

	Height	Gender	Class
$x_1$	150	F	1
$x_2$	180	M	0
$x_3$	185	M	0

$\Delta$   
 $x_1$

$\begin{matrix} 0 & 0 \\ x_2 & x_3 \end{matrix}$

⇒ Normalization

$$\text{Height} \rightarrow \frac{\text{Height} - 150}{180 - 150}$$

# Beware

## Usual practice

- ▶ Normalize the whole dataset
- ▶ Learn on the training set
- ▶ Test on the test set

# Beware

## Usual practice

- ▶ Normalize the whole dataset
- ▶ Learn on the training set
- ▶ Test on the test set

NO!

## Good practice

- ▶ Normalize the training set ( $\text{Scale}_{\text{train}}$ )
- ▶ Learn from the normalized training set
- ▶ Scale the test set according to  $\text{Scale}_{\text{train}}$  and test

# Imbalanced datasets

## Typically

- ▶ Normal transactions: 99.99%
- ▶ Fraudulous transactions: not many

## Practice

- ▶ Define asymmetrical penalizations

std penalization

$$C \sum_i \xi_i$$

asymmetrical penalizations

$$C_+ \sum_{i, y_i=1} \xi_i + C_- \sum_{i, y_i=-1} \xi_i$$

# Reminder

Vapnik, 1995, 1998

## Input

$\mathcal{E} = \{(x_i, y_i)\}, x_i \in \mathbb{R}^m, y_i \in \{-1, 1\}, i = 1..n\} \quad (x_i, y_i) \sim P(x, y)$

**Output** :  $\hat{h} : \mathbb{R}^m \mapsto \{-1, 1\}$  ou  $\mathbb{R}$ .  $\hat{h}$  approximates  $y$

**Criterion** : ideally, minimize the generalization error

$$Err(h) = \int \ell(y, \hat{h}(x)) dP(x, y)$$

$\ell$  = loss function:  $1_{y \neq \hat{h}(x)}, (y - \hat{h}(x))^2$

$P(x, y)$  = joint distribution of the data.

# The Bias-Variance Tradeoff

**Choice of a model:** The space  $\mathcal{H}$  where we are looking for  $\hat{h}$ .

**Bias:** Distance between  $y$  and  $h^* = \operatorname{argmin}\{Err(h), h \in \mathcal{H}\}$ .  
the best we can hope for

**Variance:** Distance between  $\hat{h}$  and  $h^*$   
between the best  $h^*$  and the  $\hat{h}$  we actually learn

**Note :**

Only the empirical risk (on the available data) is given

$$Err_{emp,n}(\hat{h}) = \frac{1}{n} \sum_{i=1}^n \ell(y_i, \hat{h}(x_i))$$

**Principle:**

$$Err(\hat{h}) < Err_{emp,n}(\hat{h}) + \mathcal{B}(n, \mathcal{H})$$

If  $\mathcal{H}$  is “reasonable”,  $Err_{emp,n} \rightarrow Err$  when  $n \rightarrow \infty$

# Statistical Learning

## Statistical Learning Theory

Learning from a statistical perspective.

### Goal of the theory

in general

Model a real / artificial phenomenon, in order to:

- \* understand
- \* predict
- \* exploit

# General

## A theory: hypotheses $\rightarrow$ predictions

- ▶ Hypotheses on the phenomenon
- ▶ Predictions about its behavior

here, Learning  
errors

## Theory $\rightarrow$ algorithm

- ▶ Optimize the quantities allowing prediction
- ▶ Nothing practical like a good theory!

Vapnik

# General

## A theory: hypotheses $\rightarrow$ predictions

- ▶ Hypotheses on the phenomenon
- ▶ Predictions about its behavior

here, Learning  
errors

## Theory $\rightarrow$ algorithm

- ▶ Optimize the quantities allowing prediction
- ▶ Nothing practical like a good theory!

Vapnik

## Strength/Weaknesses

+ Stronger Hypotheses  $\rightarrow$  more precise predictions

BUT if the hypotheses are wrong, nothing will work

# What Theory do we need?

## Approach in expectation

one example  
breast cancer

- ▶ A set of data
- ▶  $\bar{x}^+$ : average of positive examples
- ▶  $\bar{x}^-$ : average of negative examples
- ▶  $h(x) = +1$  iff  $d(x, \bar{x}^+) < d(x, \bar{x}^-)$

## Estimate the generalization error

- ▶ Data  $\rightarrow$  Training set, test set
- ▶ Learn  $\bar{x}^+$  et  $\bar{x}^-$  on the training set, measure the errors on the test set

# Classical Statistics vs Statistical Learning

## Classical Statistics

- ▶ Mean error

## We want guarantees

- ▶ PAC Model Probably Approximately Correct
- ▶ What is the probability that the error is greater than a given threshold?

# Example

Assume

$$Err(h) > \varepsilon$$

What is the probability that  $Err_{emp,n}(h) = 0$ ?

$$\begin{aligned} Pr(Err_{emp,n}(h) = 0, Err(h) > \varepsilon) &= (1 - Err(h))^n \\ &< (1 - \varepsilon)^n \\ &< \exp(-\varepsilon n) \end{aligned}$$

# Example

Assume

$$Err(h) > \varepsilon$$

What is the probability that  $Err_{emp,n}(h) = 0$ ?

$$\begin{aligned} Pr(Err_{emp,n}(h) = 0, Err(h) > \varepsilon) &= (1 - Err(h))^n \\ &< (1 - \varepsilon)^n \\ &< \exp(-\varepsilon n) \end{aligned}$$

Hence, in order to guarantee a risk  $\delta$

$$Pr(Err_{emp,n}(h) = 0, Err(h) > \varepsilon) < \delta$$

# Example

Assume

$$Err(h) > \varepsilon$$

What is the probability that  $Err_{emp,n}(h) = 0$ ?

$$\begin{aligned} Pr(Err_{emp,n}(h) = 0, Err(h) > \varepsilon) &= (1 - Err(h))^n \\ &< (1 - \varepsilon)^n \\ &< \exp(-\varepsilon n) \end{aligned}$$

Hence, in order to guarantee a risk  $\delta$

$$Pr(Err_{emp,n}(h) = 0, Err(h) > \varepsilon) < \delta$$

The error should not be greater than

$$\varepsilon < \frac{1}{n} \ln \frac{1}{\delta}$$

# Statistical Learning

## Principle

- ▶ Find a bound on the generalization error
- ▶ Minimize the bound.

## Note

$\hat{h}$  should be considered as a random variable, depending on the training set  $\mathcal{E}$  and the number of examples  $n$ .

$\hat{h}_n$

## Results

- deviation of the empirical error

$$Err(\hat{h}_n) \leq Err_{emp,n}(\hat{h}_n) + \mathcal{B}_1(n, \mathcal{H})$$

- bias-variance

$$Err(\hat{h}_n) \leq Err(h^*) + \mathcal{B}_2(n, \mathcal{H})$$

# Approaches

## Minimization of the empirical risk

- Model selection: Choose hypothesis space  $\mathcal{H}$
- Choose  $\hat{h}_n = \operatorname{argmin}\{Err_n(h), h \in \mathcal{H}\}$

beware of overfitting

## Minimization of the structural risk

Given  $\mathcal{H}_1 \subset \mathcal{H}_2 \subset \dots \subset \mathcal{H}_k$ ,

$$\text{Find } \hat{h}_n = \operatorname{argmin}\{Err_n(h) + \operatorname{pen}(n, k), h \in \mathcal{H}_k\}$$

Which penalization?

## Regularization

$$\text{Find } \hat{h}_n = \operatorname{argmin}\{Err_n(h) + \lambda \|h\|, h \in \mathcal{H}\}$$

$\lambda$  is identified by cross-validation

# Structural Risk Minimization

# Tool 1. Hoeffding bound

Hoeffding 1963

Let  $X_1, \dots, X_n$  be independent random variables, and assume  $X_i$  takes values in  $[a_i, b_i]$

Let  $\bar{X} = (X_1 + \dots + X_n)/n$  be their empirical mean.

## Theorem

$$\Pr(|\bar{X} - \mathbb{E}[\bar{X}]| \geq \varepsilon) \leq 2 \exp \left( - \frac{2\varepsilon^2 n^2}{\sum_{i=1}^n (b_i - a_i)^2} \right)$$

where  $\mathbb{E}[\bar{X}]$  is the expectation of  $\bar{X}$ .

# Hoeffding Bound (2)

**Application:** if

$$Pr(|Err(g) - Err_n(g)| > \varepsilon) < 2e^{-2n\varepsilon^2}$$

then with probability at least  $1 - \delta$

$$Err(g) \leq Err_n(g) + \sqrt{\frac{\log 2/\delta}{2n}}$$

but this does not say anything about  $\hat{h}_n$ ...

**Uniform deviations**

$$|Err(\hat{h}_n) - Err_n(\hat{h}_n)| \leq \sup_{h \in H} |Err(h) - Err_n(h)|$$

- if  $\mathcal{H}$  is finite, consider the sum of  $|Err(h) - Err_n(h)|$
- if  $\mathcal{H}$  is infinite, consider its trace on the data

# Statistical Learning. Definitions

Vapnik 92, 95, 98    **Trace of  $\mathcal{H}$  on  $\{x_1, \dots, x_n\}$**

$$Tr_{x_1, \dots, x_n}(\mathcal{H}) = \{(h(x_1), \dots, h(x_n)), h \in \mathcal{H}\}$$

## **Growth Function**

$$S(\mathcal{H}, n) = \sup_{(x_1, \dots, x_n)} |Tr_{x_1, \dots, x_n}(\mathcal{H})|$$

# Statistical Learning. Definitions (2)

## Capacity of an hypothesis space $\mathcal{H}$

If the training set is of size  $n$ , and some function of  $\mathcal{H}$  can have “any behavior” on  $n$  examples, nothing can be said!

$\mathcal{H}$  **shatters**  $(x_1, \dots, x_n)$  iff

$$\forall (y_1, \dots, y_n) \in \{1, -1\}^n, \exists h \in \mathcal{H} \text{ s.t. } \forall i = 1 \dots n, h(x_i) = y_i$$

## Vapnik Cervonenkis Dimension

$$VC(\mathcal{H}) = \max \{n; (x_1, \dots, x_n) \text{ shattered by } \mathcal{H}\}$$

$$VC(\mathcal{H}) = \max\{n / S(\mathcal{H}, n) = 2^n\}$$

# A shattered set

3 points in  $\mathbb{R}^2$

$\mathcal{H}$  = lines of the plane

# Growth Function of linear functions over $\mathbb{R}^{20}$

$$S(\mathcal{H}, n) \times \frac{1}{2^n} \text{ vs } n$$

The growth function is exponential w.r.t.  $n$  for  $n < d = VC(\mathcal{H})$ , then polynomial (in  $n^d$ ).

# Theorem, separable case

$\forall \delta > 0$ , with probability at least  $1 - \delta$

$$Err(h) \leq Err_n(h) + \sqrt{2 \frac{\log(S(H, 2n)) + \log(2/\delta)}{n}}$$

## Idea 1: Double sample trick

Consider a second sample  $\mathcal{E}'$

$$Pr(\sup_h (Err(h) - Err_n(h)) \geq \varepsilon) \leq$$

$$2Pr(\sup_h (Err'_n(h) - Err_n(h)) \geq \varepsilon/2)$$

where  $Err'_n(h)$  is the empirical error on  $\mathcal{E}'$ .

# Double sample trick

- ▶ There exists  $h$  s.t.
- ▶ A:  $Err_{\mathcal{E}}(h) = 0$
- ▶ B:  $Err(h) \geq \varepsilon$
- ▶ C:  $Err_{\mathcal{E}'} \geq \frac{\varepsilon}{2}$

$$\begin{aligned} P(A(h) \& C(h)) &\geq P(A(h) \& B(h) \& C(h)) \\ &= P(A(h) \& B(h)) \cdot P(C(h) | A(h) \& B(h)) \\ &\geq \frac{1}{2} P(A(h) \& B(h)) \end{aligned}$$

## Tool 2. Sauer Lemma

### Sauer Lemma

If  $d = VC(\mathcal{H})$

$$S(\mathcal{H}, n) = \sum_{i=1}^d \binom{n}{i}$$

For  $n > d$ ,

$$S(H, n) \leq \left(\frac{en}{d}\right)^d$$

### Idea 2: Symmetrization

Count the permutations that swap  $\mathcal{E}$  et  $\mathcal{E}'$ .

### Summary

$$Err(h) \leq Err_n(h) + \mathcal{O}\left(\sqrt{\frac{d \log n}{n}}\right)$$
